54 A neutron shielding material.

57 Packaging employs as a neutron shielding material hydrogenated titanium-aluminum alloys having excellent thermal properties.

EP 0 119 781 A1

BACKGROUND OF THE INVENTION

1. Field of the invention:

The present invention relates to a neutron shielding material. More particularly, it relates to a neutron shielding material having excellent thermal conductivity and heat-resistant properties.

2. Description of the prior art:

As a neutron shielding material, boron nitride or boron carbide has been used. As a neutron moderator used to increase the neutron absorbence of the shielding material, hydrogen-rich materials such as water, paraffin, wood, resin or concrete have been used. However, when these materials are used as a shielding material for exothermic radioactive materials, they can only be positioned at a certain location because of the lack of heat-resistance and thermal conductivity.

Since hydrogen-stored alloys contain more hydrogen per a unit volume than water, resin, liquid hydrogen or the like used generally as materials containing hydrogen, they are preferable as neutron moderators. Eliminating the hydrogen from these hydrogen-stored alloys at a low temperature under a low pressure has been studied, but the use of these hydrogen-stored alloys as a neutron moderator in a high temperature atmosphere has not been intended.

Materials containing boron exhibit a shielding effect against the thermal neutron zone alone. Materials containing hydrogen as a neutron moderator are required for a dry-type transportation packaging

or a dry-type storage packaging for nuclear fuels containing fast neutron, and thus, have to be excellent in heat-resistance and thermal conductivity. Synthetic resins, which lack both heat-resistance and thermal conductivity, are generally used together with aluminum and/or carbon to counteract these defects.

SUMMARY OF THE INVENTION

The neutron shielding material of this invention which overcomes the above-discussed disadvantages of the prior art, comprises hydrogenated titanium-aluminum alloys. The alloys consist essentially of 0-25 percent by weight of aluminum and the remaining portion of titanium.

The neutron shielding material of this invention also comprises a hydrogenated titanium-aluminum neutron moderator and a boron nitride or boron carbide neutron absorber.

Thus, the invention described herein makes possible the objects of (1) providing a neutron shielding material which is excellent in heat-resistance and thermal conductivity; (2) providing a neutron shielding material against γ -rays coexisting with neutrons; and (3) providing a neutron shielding material which is powdery thereby being easy for handling and applicable to any design.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a partly sectional side view of a packaging wherein a neutron shielding material according to this invention is applied.

Figure 2 is a transverse sectional view of the packaging in Figure 1.

Figure 3 is a partly sectional side view of another packaging.

Figure 4 is a transverse sectional view of the packaging in Figure 3.

Figure 5 is an arrangement of neutron shielding materials, according to this invention, in the packaging body.

Figure 6 is a graph showing the relationship between the aluminum content and the amount of stored hydrogen in hydrogenated titanium-aluminum alloys.

Figure 7 is a graph showing a comparison of the different shielding effects of hydrogenated titanium-aluminum alloys and boron nitride.

Figure 8 is a graph showing a comparison of the different shielding effects of hydrogenated titanium-aluminum alloys, boron nitride and synthetic resins.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Of the titanium-aluminum alloys such as Ti_2-Al , Ti_3-Al_2 and Ti_3-Al , the Ti_3-Al alloy is preferable because it contains a large amount of hydrogen and stores the hydrogen at up to approximately $600^{\circ}C$. These titanium-aluminum alloys, containing aluminum in the range of 0 to 25% by weight and the remaining portion of titanium, are used as a neutron moderator together with a neutron absorber, an example of which is boron nitride or boron carbide. Boron nitride and boron carbide are so excellent in thermal conductivity that they can be employed as a neutron absorber for transportation packaging or storage packaging, for nuclear fuels, made of a cast iron or a cast steel. Also, they can be produced as a powder so that they can be molded into a desired shape. When they are used together with the aforementioned titanium-aluminum alloys, the neutron absorbence is increased thereby resulting in a neutron shielding material, having an excellent thermal conductivity, which exhibits a high shielding effect in the entire neutron spectrum area and can be continuously used for a long period of time at a temperature of as high as $500^{\circ}C$.

Figures 1 and 2 show a packaging for a shielding material according to this invention, which comprises a packaging body 1 made of cast iron or cast steel wherein a bottom 20 is united with a shell 2. The open end of the shell 2 is sealed with the inner lid 10 and the outer lid 11 through a gasket (not shown). At both ends on the surface of the shell 2, trunnions 9 are disposed. Reference numerals 5 and 6

indicate a shock absorbing cover. The packaging body 1 contains a basket 4 to charge radioactive materials therein. The basket 4 is placed in a tube 5. A shielding material 6 is injected in a space between the basket 4 and the tube 5, and a second shielding material 7 is injected between the tube 5 and the shell 2. The shielding materials may be also disposed within the bottom 20 of the shell 2. On the outer surface of the shell 2, plural fins 8 are disposed to dissipate heat from the shielding materials. These fins may be circumferentially disposed on the packaging body 1.

Figures 3 and 4 show another packaging 1, wherein a shielding material 6 is injected in a space between a basket 4 and a tube 5, and a second shielding material 7 is disposed on the outside of the shell 2. The outer side of the second shielding material 7 is covered by a tube 71.

The shielding material 6, which is, for example, made of a mixture of the $Ti_3-Al-Hn$ alloy powder with boron nitride powder or boron carbide powder, serves as a moderator and an absorber of fast neutrons thereby exhibiting an excellent shielding effect. The second shielding material 7, which is, for example, made of boron nitride powder or boron carbide powder, mainly serves to absorb neutrons thereby exhibiting a shielding effect. Both of the shielding materials 6 and 7 may be made of sintered compacts of boron nitride powder and/or boron carbide powder.

According to the packaging 1 shown in Figure 1 to 4, respectively, neutron energy from the basket 4 is absorbed to a great extent by the shielding

material 6 and the remaining small amount of energy is absorbed by the second 7. Thus, the thickness of the shell 2 may be reduced thereby enabling a reduction of weight of the packaging body. Heat-dissipation from the basket 4 is not prevented because of the superior heat-resistance and heat-conductivity of the shielding materials 6 and 7.

The sintered compact constituting the shielding materials 6 and 7 may be disposed as one body or a combination of pieces shown in Figure 5, wherein the shielding material 60 is disposed with alternations of block 6a and block 6b and the second 70 is disposed with alternations of block 7a and block 7b. The block 6a may be of a sintered compact of Ti_3-Al powder and the block 6b may be of a sintered compact of boron nitride powder or boron carbide powder. Alternatively, both the blocks 6a and 6b may be of the same sintered compacts.

The amount of hydrogen stored by the titanium-aluminum alloys and the storing and releasing properties of the alloys depend upon the amount of aluminum in the alloys as seen from the below-mentioned Table and Figure 6.

0119781

Sample No.	Hydrogen Stored Ti-Al Alloys	Aluminum Content in Ti-Al Alloys (gr/gr x100%)	Amount of Hydrogen Stored by Ti-Al Alloys (gr/cm ³)	Properties
1	Ti-H ₂	0	0.188	store at above 500°C Release at above 670°C
2	Ti ₁₉ -Al-H ₃₆ .2	2.88	0.172	Store at ordinary Temp. Release at above 600°C
3	Ti ₉ -Al-H ₁₆ .3	5.89	0.153	same as above
4	Ti ₅ -Al-H ₉ .06	10.1	0.140	same as above
5	Ti ₃ -Al-H ₅ .18	15.8	0.118	same as above
6	Ti _{2.6} -Al-H ₃ .92	17.8	0.101	same as above
7	Ti ₂ -Al-H ₂ .25	22.0	0.075	same as above
8	Ti ₃ -Al ₂ -H ₀ .42	27.3	0.008	Hydrogen is contained in a solid solution state.
9	Ti-Al-H ₀ .068	36.0	0.003	same as above

The above Table and Figure 6 indicate that:

(1) When the amount of aluminum in the alloy is less, the amount of hydrogen that can be stored is greater;

(2) When the amount of aluminum in the alloys becomes zero, i.e. titanium alone, the storing and the releasing of hydrogen are achieved at a high temperature. The amount of hydrogen that can be stored is the largest;

(3) As a small amount of aluminum is contained in the alloys, the hydrogen storing temperature is remarkably decreased to approximately ordinary temperature while the hydrogen releasing temperature is maintained at a high temperature; and

(4) When aluminum is greater than 25%, the amount of hydrogen that can be stored is remarkably reduced.

Since the standard of the hydrogen content which is effective as a neutron shielding is 0.07grH/cc or more for liquid hydrogen and 0.11gr/cc or more for water (H_2O), the most effective shielding materials are sample Nos.1 to 5 in the above Table, wherein the aluminum content ranges from 0 to 22%. Practically, shielding materials of aluminum content up to 25% are also acceptable.

The property of the alloy according to the present invention is classified, depending on the content of aluminum, into the following three categories:

- 1) The first category: (the content of Al= not less than 0 to not more than 6 wt %)

Hydrogen can be easily stored at a commercial low temperature and the amount of hydrogen to be stored becomes great. Hydrogen is released at a high temperature of about 600 C and the good heat resistance can be enjoyed.

2) The second category: (the content of Al= 0 %)

The amount of hydrogen to be stored becomes the greatest. The releasing of hydrogen is achieved at a high temperature but the hydrogen storing temperature is likely to be a high temperature of about 500 C.

3) The third category: (the content of Al: 6 to 25 wt%)

Hydrogen can be easily stored at an ambient temperature and the hydrogen releasing temperature becomes enough high but the amount of hydrogen to be stored is less as compared to the above two alloys.

Figures 7 and 8 show the shielding effect at a time when the neutron shielding materials mentioned above are applied to a packaging.

The difference in a shielding effect depending upon the kind of neutrons is shown in Figure 7 wherein the zone A is at the generation source, the zone B is the steel packaging wall, the zone C is a neutron shielding wall and the zone D is the outside

atmosphere of the packaging. The curve 20 shows the behavior of intermediate neutrons, the curve 30 shows the behavior of fast neutrons and the curve 40 shows the behavior of heat neutrons in the zones A and B. Figure 7 indicates that the neutrons at the generation source, zone A, are substantially fast and intermediate neutrons.

These neutrons decay while passing through the shielding wall. When the shielding material is made of a boron nitride alone, the intermediate neutrons exhibit a decay curve as shown by the curve 21, while when the shielding material is made of a hydrogenated titanium-aluminum alloy plus 10% boron nitride, the intermediate neutrons decay as shown by the curve 22. The fast neutrons exhibit a decay curve as shown by the curve 31 when the shielding material is made of boron nitride alone, while they decay as shown by the curve 32 when the shielding material is of a hydrogenated titanium-aluminum alloy plus 10% boron nitride.

The heat neutrons show a decay curve 41 when the shielding material is made of the above-mentioned alloy, while they decay as shown in the curve 42 using a shielding material made of boron nitride alone. This can be explained by the phenomenon that the neutrons change from fast neutrons into the heat neutrons due to a decay effect of the alloy and thus the heat neutrons rapidly increase. Although the degree of the decay of the curve 41 is slight as compared with that of the curve 42, the absolute value of the heat neutrons shown by the curve 41 is 2 orders lower than for the fast and/or the intermediate neutrons shown by the curves 22 and 32. The heat neutrons shown by the curve 41 decay with the

additional use of a shielding material of boron nitride.

Figure 8 shows the shielding effect of the radioactive influence on the human body, wherein the curve 50 indicates the neutron dose rate and the curve 55 the γ -ray dose rate.

As seen from Figure 8, the neutron dose rate shown by the curve 50 decays as shown in the curve 51 when the shielding material is of boron nitride alone, and as shown in the curve 52 when the shielding material is of a synthetic resin alone, while it decays as shown in the curve 53 when the shielding material is of a hydrogenated titanium-aluminum alloy plus 10% boron nitride. Also, the γ -ray dose rate shown by the curve 55 decays remarkably as shown in the curve 54 when a hydrogenated titanium-aluminum alloy plus 10% boron nitride is used as the shielding material. These shielding effects are not expected from the use of boron nitrides and/or synthetic resins.

It is understood that various other modification will be apparent to and can be readily made by those skilled in the art without departing from the scope and spirit of this invention. Accordingly, it is not intended that the scope of the claims appended hereto be limited to the description as set forth herein, but rather that the claims be construed as encompassing all the features of patentable novelty which reside in the present invention, including all features which would be treated as equivalents thereof by those skilled in the art to which this invention pertains.

CLAIMS

1. A neutron shielding material comprising hydrogenated titanium-aluminum alloys.

2. A neutron shielding material according to claim 1, wherein said hydrogenated titanium-aluminum alloys consist essentially of 0-25 percent by weight of aluminum and the remaining portion of titanium.

3. A neutron shielding material comprising a hydrogenated titanium-aluminum neutron moderator and a boron nitride or boron carbide neutron absorber.

4. A neutron shielding material according to claim 2, wherein said hydrogenated titanium-aluminum alloys consist essentially of not less than 0 to not more than 6 percent by weight of aluminum and the remaining portion of titanium.

5. A neutron shielding material according to claim 2, wherein said hydrogenated titanium-aluminum alloys consist essentially of 6 to 25 percent by weight of aluminum and the remaining portion of titanium.
